Ensuring Safe Transportation of Used Nuclear Fuel

Transportation of used nuclear fuel to a centralized facility is a necessary component of implementing Adaptive Phased Management (APM) for the long-term management of Canada's used nuclear fuel. The Nuclear Waste Management Organization (NWMO) recognizes that people have questions and concerns about the transport of used nuclear fuel. However, Canadian and international experience demonstrates that used nuclear fuel can be transported safely.

Introduction

Used nuclear fuel is currently stored at the sites of the nuclear power reactors where it is produced, and at research sites. Figure 1 shows these reactor storage sites. In addition, small amounts of fuel are present inside university research reactors in Alberta, Saskatchewan, Ontario, Quebec and Nova Scotia.

The Adaptive Phased Management approach for the long-term care of used nuclear fuel will ultimately include a centralized facility for the used nuclear fuel. Transportation to this facility from the current sites will therefore be needed. Options for transportation are by road, rail or water modes (i.e. truck, train or ship). In the case of water transport, road or rail links would be needed, in addition to docking facilities.

At present, limited amounts of used nuclear fuel are transported in Canada. However, in other countries, in particular France, the United Kingdom and Sweden, shipments of used nuclear fuel take place routinely on a large scale.

Figure 1: Current storage locations of used fuel
Transport Canada is responsible for regulating all dangerous goods that are transported within Canada. Responsibility for the regulation of transport of radioactive material is shared with the Canadian Nuclear Safety Commission (CNSC).

Other hazardous materials, such as gasoline, chlorine and propane, are routinely transported in Canada, including transport within heavily populated areas. There are approximately 30 million shipments of dangerous goods in Canada every year. Six million tonnes of hazardous waste are transported in Canada every year by road, rail, sea and air.

**Can Used Nuclear Fuel Be Transported Safely?**

Throughout the course of our dialogues, many citizens expressed concern about the transportation of used nuclear fuel and questioned whether it can be accomplished safely. The NWMO acknowledges this concern and the need to demonstrate the safety of any transportation system to the satisfaction of citizens before beginning to transport used nuclear fuel to a centralized long-term management facility.

The NWMO believes that with sufficient effort, resources, preparation, oversight and continued vigilance, used nuclear fuel can be transported safely. This is for a number of reasons.

**Robust Transportation Packages**

Used nuclear fuel transportation packages are massive structures, providing both protection and shielding of the used nuclear fuel.

Because of the robustness of these containers, used nuclear fuel has been transported safely for over 40 years internationally. The International Atomic Energy Agency (IAEA) has also set standards for the physical protection of nuclear material and produced guidelines for member countries to plan for and respond to emergency situations.

The package shown in Figure 2 currently certified in Canada for used nuclear fuel transportation consists of a solid stainless steel box, with walls nearly 30 cm thick and a lid attached by 32 bolts. This cask can carry about 4 tonnes of used nuclear fuel, and the loaded package weighs about 35 tonnes.

Each package design must meet a series of severe performance requirements specified by the regulations to demonstrate the ability to withstand impact, fire and immersion in water. The test requirements for normal and accident conditions of transport are shown in Table 1.

International Experience

While used nuclear fuel has not been transported widely in Canada, government, regulators and commercial organizations around the world have extensive experience transporting radioactive and nuclear materials, and with regulating it for safety and security. Government and independent experts in many countries, most notably the United States, the European Union and Japan, as well as the IAEA, have also regularly examined and researched safety issues concerning radioactive material transport. A large body of technical data exists which can be drawn on by regulators, utilities, politicians and the public in preparing any future plans for the transportation of used fuel. This information has direct application and relevance because Canada, as a member of the IAEA, is obliged to meet the same level of international standards that have been the subject of this study and analysis.

Canada's Regulatory Framework

In Canada, the movement of radioactive materials, including used nuclear fuel, other nuclear wastes, industrial radiography sources and medical isotopes, is regulated by the Transport Dangerous Goods Directorate of Transport Canada and the CNSC.

For shipment of radioactive materials, Transport Canada is primarily responsible for:

» establishing and enforcing transportation requirements for the consignors and carriers;
» establishing requirements and undertaking compliance inspections for aspects such as training and documentation;
» setting and enforcing requirements for Emergency Response Assistance Plans.

<tr>
<th>CONDITIONS</th>
<th>TESTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal transport conditions</td>
<td>» Free drop test: package is dropped 0.3 metre onto an unyielding surface</td>
</tr>
<tr>
<td></td>
<td>» Penetration test: a 6-kilogram bar is dropped 1 metre onto the package</td>
</tr>
<tr>
<td></td>
<td>» Stacking test: a compressive load equivalent to 5 times the mass of the package (packaging plus used fuel) is applied to the package</td>
</tr>
<tr>
<td></td>
<td>» Water spray test: exposure to rainfall of approximately 5 cm/h for at least 1 hour</td>
</tr>
<tr>
<td>Accident transport conditions</td>
<td>» Free drop test: package is dropped 9 metres onto an unyielding surface</td>
</tr>
<tr>
<td></td>
<td>» Penetration test: package is dropped 1 metre onto a rigid vertical bar</td>
</tr>
<tr>
<td></td>
<td>» Thermal test: package is exposed for 30 minutes to a hydrocarbon fuel/air fire with an average temperature of 800°C</td>
</tr>
<tr>
<td></td>
<td>» Water immersion test: package is exposed for 8 hours to a 15-metre head of water</td>
</tr>
</tbody>
</table>
The CNSC is primarily responsible for:

» setting transportation package performance requirements;
» certification of transportation package designs;
» establishing and enforcing the radiation protection program for carriers;
» investigating in the event of a dangerous occurrence;
» all aspects of physical security measures.

Transport Canada’s regulations for the transportation of dangerous goods have been adopted at the provincial and territorial levels through administrative agreements.

The design of every used nuclear fuel transportation package must be certified by the CNSC to ensure that all regulatory requirements have been met. All users of the package must be registered by the CNSC. Additionally, a Licence to Transport requiring pertinent security and emergency response details must be obtained from the CNSC.

**Transportation Experience**

In Canada, about one million packages of radioactive materials are shipped each year. Most contain medical isotopes. Limited amounts of used nuclear fuel are transported in Canada. These have included the movement of demonstration reactor fuel to Chalk River Laboratories for storage, and the periodic movement of a few used nuclear fuel bundles each year from nuclear power stations to Chalk River Laboratories for research and examination purposes.

Transportation of radioactive materials takes place routinely around the world. Safety provisions are similar in all countries and are based on regulatory standards developed by the IAEA. The IAEA regularly reviews its model transport regulations, assessing both the adequacy of the provisions and level of compliance with the requirements. There have been no reported transport accidents with serious radiological consequences. The safety record established by the IAEA requirements over 40 years compares favourably with that of the shipment of all other hazardous materials.

It has been estimated by the IAEA that throughout the world, about 20 million shipments of radioactive material are made each year. Examples of the vehicles and equipment used for transportation of used nuclear fuel in Canada and elsewhere are shown in Figures 3 – 5.

In the United States, nearly 3,000 shipments of commercial used nuclear fuel have been transported over 2.5 million km in the last 40 years [US DOE 2005]. During that period, there were nine transport accidents involving packages of the type required for highly radioactive materials such as used nuclear fuel. In no case did any of these packages release their radioactive contents.

The United Kingdom and France transport a combined average of 650 shipments of used nuclear fuel or high-level waste per year, primarily by rail. Used nuclear fuel and high-level reprocessing waste are also transported by sea between Europe and Japan, with 170 shipments in the last 30 years [PNTL 2008]. Sweden routinely ships used nuclear fuel between its nuclear power plants and interim storage facility, with 30-40 trips per year [SKB 2008].

Figure 4: Rail car with a transportation cask used in Europe (left); the rail-to-road transfer facility near La Hague in France (below). Photos from Areva.
Serious accidents involving non-nuclear hazardous material have occurred. What if used nuclear fuel had been involved in a rail derailment or tunnel fire? Studies of 12 actual severe accidents, none involving radioactive material, showed that the integrity of used nuclear fuel casks would have been maintained if they had been present. This and similar studies have consistently shown that the levels of risk are very low regardless of whether used nuclear fuel is transported over land or by sea.

Implementing Adaptive Phased Management

The regulatory regime for regulation and oversight of used nuclear fuel transportation is well-established. There is practical experience in Canada and internationally. The NWMO believes that with sufficient effort, resources, preparation, oversight and continued vigilance, used nuclear fuel can be transported safely.

The logistics of transportation would depend on the location of the centralized site. For some potential site locations, the options for transportation routes could be very limited, while for other locations, a number of alternatives might be explored. Multiple routes might be used.

For long-term management, the number of shipments of used nuclear fuel from the reactor sites to the central facility during the operating period would be:

- **Road**: about 53 road shipments/month, or
- **Rail**: about 5 rail shipments/month + about 36 road shipments/month, or
- **Water**: about 2 water shipments/month + about 36 road shipments/month.

In summary, the NWMO acknowledges the concerns of many citizens about the transportation of used nuclear fuel and the need to demonstrate the safety of any transportation system to the satisfaction of citizens before beginning to transport used nuclear fuel to a centralized long-term management facility. The NWMO understands that decisions on risk and safety are societal ones. On the basis of the work which the NWMO has conducted during this study, including the commissioning of background papers, and the discussions it has had with nuclear waste management organizations in other countries, the NWMO believes that used nuclear fuel can be transported safely. Adequate effort, resources, preparation, oversight and continued vigilance are necessary requirements of any plan for transportation of used nuclear fuel and, therefore, must be critical elements of any implementation plan for a management approach.
